Abstract: To show the effectiveness or limitation of using library loan records for book recommendation, we implemented the collaborative filtering system (henceforth LLR system) which is similar to that of Harada & Masuda (2010) and compared its performance with Amazon. It was found that LLR system could not outperform Amazon. Library loan records contain users' privacy and collaborative filtering usually requires much computer resources. We should pay attention to whether LLR system is really effective enough to worth its cost.

Keywords: Library Loan Records, Book Recommendation, Collaborative Filtering, Amazon, Privacy

I. INTRODUCTION

Library loan records are attracting people's attentions who are trying to produce new library services. Among them is the book recommendation system using collaborative filtering based on loan records (henceforth LLR system). However, library loan records contain users' privacy and collaborative filtering usually requires much computer resources. Is it really effective enough to worth its cost? Against this background, we implemented LLR system which was similar to that of Harada & Masuda (2010) and compared its performance with Amazon. If the latter outperformed the former, we might be able to say that Amazon is an inexpensive alternative for book recommendation system. The loan records we used for our experiment were those of one Japanese university library.

II. METHODS

A. Recommendation Algorithm

In this paper, we call the user to whom we would like to recommend books as "active user". Similarly, we call users whose library loan records are used for recommendation as "sample users".

In brief, our system calculates the similarity of library loan records between active user and sample users and recommends books that several sample users who are similar to active user have borrowed (and active user has not borrowed). For instance, if a sample user exists who borrowed books {a, b, c, d, e} and the active user has borrowed books {a, b, c, d}, our system recommends book e to the active user. The detail is as follows:

(a) Our system calculates the similarity score p_{ai} be-

tween active user a and sample user i as follows:

$$p_{ai} = \frac{\sum_{k \in Y_{ai}} (s_{ak} - \bar{s}'_a)(s_{ik} - \bar{s}'_i)}{\sqrt{\sum_{k \in Y_{ai}} (s_{ak} - \bar{s}'_a)^2} \sqrt{\sum_{k \in Y_{ai}} (s_{ik} - \bar{s}'_i)^2}} \quad (1)$$

where Y_{ai} represents a set of books that the active user a and sample user i evaluated in common (in fact, Y_{ai} represents all the books the library holds as we mention later). s_{ij} represents a score the user i gave to the book j . \bar{s}'_i represents the average score that the user i gave to the books.

(b) Then our system recommends book j whose score \hat{s}_{aj} is high:

$$\hat{s}_{aj} = \sum_{i \in X} p_{ai}(s_{ij} - \bar{s}'_i) \quad (2)$$

where X represents all the sample users. The score we defined is slightly different from that of Kamishima (2008) and Resnick et al. (1994). In order to adopt score definition by Harada & Masuda (2010), we regarded the books which were not borrowed were scored 0 by the user. Therefore, all books the library holds were regarded to be scored by both active user and sample users (otherwise, we cannot calculate p_{ai}).

According to Harada & Masuda (2010), the scores are defined as follows: (1) the score the sample user gave to book is either 0 (he/she has not borrowed that book) or 1 (borrowed that book). (2) the score the active user gave were determined based on the subject of the book. The books which have the most popular Japanese decimal classification number (henceforth NDC. It ranges from 0 to 9) among the set of books the user borrowed are given score 1. The second, third and fourth most popular books are given scores 0.5, 0.25, 0.125, ..., respectively. The loan records are divided by month according to Harada & Masuda (2010). Therefore, for instance, sample user X's loan record in April 2009 and in May 2009 are regarded as different loan records of different sample users.

B. Library Loan Records

The library loan records of one Japanese university library were used for our experiment. Each record consists of user ID, book ID, the dates the book was borrowed/returned, NDC of the book, etc. These records

were collected from 2006 to 2010. The number of them is approximately two million.

C. Evaluation

Four students were asked to be subjects of our experiment. Two of them are Ph.D. course students (henceforth students A and B) and the others are undergraduates of fourth grade (students C and D). They all belong to the library and information science course. Student A and B borrowed 58 and 207 books (tokens) during the previously mentioned period. Students C and D borrowed 82 and 11 books, respectively.

The subjects were asked to indicate one book R which they were interested in and the library holds. Then:

- (1) We put it into LLR system. The system recommends six books based on R and loan records of each subject.
- (2) We put R into Amazon.co.jp and obtain six books that the Amazon recommends as "The customer who bought R also bought these six books". Then the books that the library holds among these six were chosen for the final recommendation.

These two sets of recommended books were mixed and shown to the subjects. They were asked to rate them 3, 2, 1, 0 and x as follows:

- 3: I already have that book (the best recommendation).
- 2: I am strongly interested in that book (second best).
- 1: I am interested in that book.
- 0: I am not interested in that book.
- x: I have no idea.

III. RESULTS & DISCUSSIONS

The rates given to each recommended book by subjects A, B, C and D are shown in Tabs. 1, 2, 3 and 4, respectively. We can see in Tab. 1, for instance, that graduate student A gave "1" to four books (i.e., "Libraries in Finland & Sweden", "Introduction to Cultural Informatics", ...) which were recommended by LLR system and its ratio is 67% (=4/6). Likewise, she gave "3" to three books (i.e., "Orientalism Vol.1", "Orientalism Vol.2", ...) which were recommended by Amazon and its ratio is 60% (=3/5). By comparing the rates given to books which were recommended by LLR and Amazon, we can see that Amazon obtained relatively better scores than LLR and thus showed better performance. For instance, while undergraduate student D showed no interest in books recommended by LLR, she gave rates "2" and "1" to one and two books recommended by Amazon, respectively (in Tab. 4).

As we previously mentioned, undergraduate student D borrowed only 11 books from library (although she is in the fourth grade, i.e., she has been in university three years and a half). To such students, LLR system cannot recommend adequate books. Unfortunately, we think she is not an exceptional case in Japan. While the dif-

ference in recommendation performance between LLR and Amazon to student B (who borrowed 207 books) is small, those to students A and B are not negligible.

The loan records in university libraries have inherent weakness compared to Amazon purchase records. Borrowing books in libraries is free of charge and some users carelessly borrow books which have no relation to each other and to their needs. That brings noise to recommendation system. Besides, students borrow various books together which are unrelated especially in the end of the semester to prepare term reports and term exams. That might bring another noise to recommendation.

IV. CONCLUSIONS

To show the effectiveness or limitation of using library loan records for book recommendation, we implemented the collaborative filtering system which is similar to that of Harada & Masuda (2010) and compared its performance with Amazon. As we were concerned about, the LLR system could not outperform Amazon. We do not claim that libraries should not adopt new technology but library loan records contain users' privacy and collaborative filtering usually requires much computer resources. We should pay attention to whether LLR system is really effective enough to worth its cost.
